

**Experimental and Computational Spectroscopic Studies of the Isomers
and Conformations of Dibenzylideneacetone**

By

Zachary B. Richardson

A Major Qualifying Project

Submitted to the Faculty

Of the

Worcester Polytechnic Institute

In partial fulfillment of the requirements for the

Degree of Bachelor of Science

In

Chemistry

APPROVED:

ABSTRACT

This project examines the conformational isomers of dibenzylideneacetone through infrared and UV-vis absorption spectra as well as quantum molecular modeling. Experiments followed the procedures of previously published experiments of dibenzylideneacetone, in hopes of interpreting the results.

ACKNOWLEDGEMENTS

Thanks to Professor Connors for taking me into this project and not giving up on me.

Thanks to Dr. Christopher Zoto for helping me along the way, Worcester Polytechnic institute for four amazing years and change and my ~~girlfriend~~ fiancée Sarah-Beth for being the greatest person on earth the last two years and four months.

Introduction

Dibenzylideneacetone, here for known as DBZA is a ketone whose formula is $C_{17}H_{14}O$.

DBZA is a flaky, low density yellow solid at room temperature and only dissolves in a small number of solvents. The physical properties of DBZA are as shown as compared to benzaldehyde and acetone:

| Material | Benzaldehyde | Acetone | (E,E)- Dibenzylideneacetone |
|-------------------------------|----------------|--------------------------------|--------------------------------|
| Molecular weight [g/mol] | 106.12 | 58.08 | 234.30 |
| Density [g/ml] | 1.05 | 0.79 | - |
| Melting point [°C] | | | 107 – |
| n [mmol] | 47.2 | 23.0 | 12.1 |
| Mass [g] | 5.01 | 1.34 | 10.45 |
| Volume [ml] | 4.77 | 1.70 | - |
| Neq | 2 | 1 | - |
| Company | Acros Organics | Fluka | - |
| Purity | > 98% | > 99.7% | - |
| Risk and Safety Statements | R 22 S 24 | R 11-36-66-67- 39/23/24/25- | S 22-24/25 |

Table 1: DBZA Physical properties compared to its components. (Vaucher 2010)

DBZA is formed from an aldol condensation where benzaldehyde (2 mole eq.) and acetone (1 mole eq.) in sodium hydroxide base and an ethanol solvent (Vaucher). DBZA is used as a sun screening agent due to sunlight eventually isomerizing the ketone into cyclobutanes (Huck and Leigh). DBZA is also used extensively in inorganic chemistry as a ligand for Palladium (0) as well as Platinum (0), both very rare and unreactive metals. Tris (Dibenzylideneacetone)

dipalladium has been proven effective against melanoma growth (Bhandarkar et al). This compound's uses have warranted further study of its properties.

Experimental

DBZA is a compound with two rotational degrees of freedom, thus DBZA exhibits three conformational isomers under various conditions (Venkateshwarlu and Subrahmanyam). These three rotational isomers, cis-cis (here forth referred to as EE), cis-trans (here forth referred to as ZE), and trans-trans (here forth referred to as ZZ) differ at the second and fourth carbons on the central 1,5-dibenzylpentadi-2,4-ene-3-one chain. Tanaka et al hypothesized the bond angles and lengths for all three isomers based on standard bond length knowledge for C=O, C-H and C=C bonds in unsaturated compounds. At first the EE was believed to be the dominant form (Tanaka et al), and its structure can be seen here from ChemDraw.

Figure 1: ChemDraw structure of the major conformer of DBZA

This hypothesis stemmed from room temperature Kerr values studies and visible polarization values in order to determine the main conformer in solid DBZA (Bramley and Le

Fèvre). Also, these conformers have widely varying energies of formation, as noted by Tanaka, et al in their nuclear magnetic resonance study of the compound at room temperature:

INDO total energies ΔE_t , electronic energies ΔE_e , and core repulsion energies ΔE_c of the three planar conformations of DBA (in eV)

| Conformation | ΔE_e | ΔE_c | ΔE_t |
|----------------------|--------------|--------------|--------------|
| <i>s-cis,cis</i> | 0.000 | 0.000 | 0.000 |
| <i>s-cis,trans</i> | -224.947 | 225.075 | 0.128 |
| <i>s-trans,trans</i> | -749.426 | 757.436 | 8.010 |

The energies of the *s-cis,cis* form are taken as the base: E_e -18 445.862, E_c 14 518.070, E_t -3 927.792 eV.

Table 2: ΔE values from room temperature NMR study (Tanaka et al 1978)

Here, through NMR spectroscopy, Tanaka et al concluded that evidence was found for the room temperature presence of just two planar conformers, a major (EE) and a minor (ZE), due to the disproportionately high ΔE for a (ZZ) planar conformer. This finding relates strongly to an older infrared spectrum study, where a two conformer hypothesis was supported by a claim of two C=O region bands for DBZA in carbon tetrachloride, and the authors used dipole moments to support their hypothesis, rather than test for bond angles or electronic transitions (Tsukerman et al 1968). These studies inspired an ultraviolet spectrum study of DBZA, first at room temperature, and then at 101 K, only to discover that form ZE is actually non-planar at room temperature or higher, with a torsion angle that increases with an increase in the first $\pi^* \leftarrow \pi$ shift of location, given that in ketones this shift has the lowest energy (Hoshi et al 1986). Their UV visible spectrum in n-hexane is shown here.

Figure 2: UV Visible spectrum of concentrated and 30X diluted SBZA in n-hexane (Hoshi et al)

Armed with this knowledge, Venkateshwarlu and Subrahmanyam studied the infrared spectra of DBZA in carbon tetrachloride, chloroform and dichloromethane solvents, to discover evidence for three hypothesized conformers, EE, ZE, and a non-planar ZZ isomer.

Venkateshwarlu's and Subrahmanyam's hypothesis would be tested based on carbon-oxygen double bond frequencies observed in the IR spectrum, and how well their peaks confirm to known carbon-oxygen double bond frequencies from their researched table:

| Conformer | CCl ₄ frequency cm ⁻¹ And relative intensity | CHCl ₃ frequency cm ⁻¹ And relative intensity | CH ₂ Cl ₂ frequency cm ⁻¹ And relative intensity |
|-----------------|---|--|--|
| C=O Cis-Cis | 1676 (0.2107) | 1671 (0.1750) | 1674 (0.1644) |
| C=O Cis-Trans | 1655 (0.4676) | 1653 (0.4270) | 1654 (0.3920) |
| C=O Trans-Trans | 1650 (0.3216) | 1648 (0.3970) | 1649 (0.4430) |

Table 3: Determined C=O stretching frequencies of DBZA (Venkateshwarlu and Subrahmanyam)

They came to observe a triplet peak all three times in the C=O regions they had hypothesized, as seen here:

Figure 3. The C=O bands of DBA in different solvents. (a) CCl₄. (b) CHCl₃. (c) CH₂Cl₂.

Figure 3: Venkateshwarlu and Subrahmanyam IR results in CCl₄, CHCl₃ and CH₂Cl₂

This peak from (1655 to 1645 cm^{-1}) is a doublet whose right side intensity increased with more polar solvents, with dichloromethane being the most pronouncedly so, decreasing to chloroform and carbon tetrachloride (Venkateshwarlu and Subrahmanyam). This side of the triplet was concluded to confirm to the ZZ isomer, increased in intensity and therefore frequency with more polar solvents (Venkateshwarlu and Subrahmanyam). This strain created a skewed conformer, which is the only possible setup for the ZZ isomer they hypothesized. The increased presence of ZE and EE conformers in less polar solvents was hypothesized to be the result of steric hindrance from polar solvents of non-skewed conformers.

This skewed conformation is the result of strong π electron repulsion and the high polarity displayed by the ZZ DBZA conformer (Venkateshwarlu and Subrahmanyam 1987). The following experiments seek to confirm the findings by Venkateshwarlu and Subrahmanyam using two infrared spectra devices and the same three solvents, as well as quantum chemical modeling. The absorption spectra data will be tested for as well to confirm the Hoshi et al results. Quantum chemical modeling will be used to observe the optimized shapes and structural data of each isomer.

Structural Data

Through thorough quantum chemical modeling studies, the structures of all three conformers of DBZA were calculated at the DFT B3LYP/6-311+G(d,p) level of theory. The 6-311+G(d,p) level of theory is the largest basis set of DFT and the most accurate of the set of basis sets. The optimized forms of the conformers below were generated:

Figure 4: WebMO generated optimized forms of EE, ZE and ZZ Conformers

The skewed ZZ conformation obtained by Venkateshwarlu and Subrahmanyam became a reality, as a high bond angle between the first three carbons of the central 2,4-pentadiene-3-one chain was required to create a non-resonating and stable ZZ conformer.

Figure 5: ZZ conformer skew side view

Bond lengths and angles have also been determined at the DFT B3LYP/6-311+G(d,p) level of theory. The following bond lengths were obtained from the optimized EE conformer in air.

| Bond Number | Region | Bond Length (Å) |
|-------------|--------------|-----------------|
| R1 | R(1,2) C-C | 1.4843 |
| R2 | R(1,17) C=O | 1.2265 |

| R31 | R(24,25) C=C | 1.3883 |

Table 4: C-C, C=O, C=C, and the center C-H bond lengths for the EE Isomer

These values largely followed the predicted ones by Tanaka et al. The exceptions being that the single bonded carbon atoms along the 2,4-pentadiene-3-one chain had bond lengths that were 4 angstroms longer than the benzene carbon-carbon single bonds, and the double bonds of the 2,4-pentadiene-3-one were .552 angstroms shorter than the benzene carbon double bonds.

Bond angles were examined next for all C=C-C and C-C=O regions of the EE conformer. These angles in an air optimized structure are as follows.

| Angle | Location (All are C=C-C unless otherwise labeled) | Angle |
|-------|---|----------|
| A1 | A(2,1,17) C-C=O | 122.1456 |
| A2 | A(2,1,18) | 115.7088 |
| A3 | A(17,1,18) O=C-C | 122.1456 |
| A4 | A(1,2,3) | 121.0994 |
| A7 | A(2,3,4) | 128.1149 |
| A10 | A(3,4,5) | 118.5621 |
| A11 | A(3,4,9) | 123.3655 |
| A12 | A(5,4,9) | 118.0724 |
| A13 | A(4,5,6) | 121.1483 |
| A16 | A(5,6,7) | 119.9796 |
| A19 | A(6,7,8) | 119.653 |
| A22 | A(7,8,9) | 120.3418 |
| A25 | A(4,9,8) | 120.8049 |
| A28 | A(1,18,19) | 121.0994 |
| A31 | A(18,19,20) | 128.1149 |
| A34 | A(19,20,21) | 118.5621 |
| A35 | A(19,20,25) | 123.3655 |
| A36 | A(21,20,25) | 118.0724 |
| A37 | A(20,21,22) | 121.1483 |
| A40 | A(21,22,23) | 119.9796 |
| A43 | A(22,23,24) | 119.653 |
| A46 | A(23,24,25) | 120.3418 |
| A49 | A(20,25,24) | 120.8049 |

Table 5: C=C-C and C-C=O Bonding angles

Here, the angle is significantly more acute for the (2,1,18) region. This is due to the oxygen polar bonded onto carbon 1. The angles are significantly more obtuse where the angle ends at 5 or 20, the beginning of the benzene rings. The fact that these carbons at the end of the benzene rings are only bonded to carbons changes the angle between the bonds slightly as compared to the carbons bonded to hydrogen and two carbons.

A similar procedure was carried out for the ZE conformer, whose optimized bond lengths are as follows:

| Bond Name | Region | Bond Length (Å) |
|-----------|--------------|-----------------|
| R1 | R(1,2)C=O | 1.2278 |
| R2 | R(1,3) C-C | 1.4806 |
| R3 | R(1,18)C-C | 1.4851 |
| R4 | R(3,4)C=C | 1.3456 |
| R5 | R(3,17) C-H | 1.0853 |
| R6 | R(4,5)C-C | 1.4654 |
| R7 | R(4,16) C-H | 1.0861 |
| R8 | R(5,6) C-C | 1.4049 |
| R9 | R(5,10) C=C | 1.4065 |
| R10 | R(6,7) C=C | 1.3917 |
| R12 | R(7,8) C-C | 1.3929 |
| R14 | R(8,9) C=C | 1.397 |
| R16 | R(9,10) C-C | 1.3885 |

| R23 | R(20,21) C-C | 1.4068 |
| R24 | R(20,25) C=C | 1.4052 |
| R25 | R(21,22) C=C | 1.3885 |
| R27 | R(22,23) C-C | 1.3972 |
| R29 | R(23,24) C=C | 1.3929 |
| R31 | R(24,25) C-C | 1.3918 |

Table 6: C-C, C=O, C=C, and the center C-H bond lengths for the ZE Isomer

The values were practically identical to those of the EE isomer. The ZE isomer had carbon-carbon-carbon and oxygen-carbon-carbon bond angles as such:

| Angle | Location (All are C=C-C unless otherwise labeled) | Angle |
|-------|---|----------|
| A1 | A(2,1,3) O=C-C | 118.5711 |
| A2 | A(2,1,18) O=C-C | 121.486 |
| A3 | A(3,1,18) C-C=C | 119.943 |
| A4 | A(1,3,4) | 126.9345 |
| A7 | A(3,4,5) | 127.0815 |
| A10 | A(4,5,6) | 118.6523 |
| A11 | A(4,5,10) | 123.2501 |
| A12 | A(6,5,10) | 118.0976 |
| A13 | A(5,6,7) | 121.1799 |
| A16 | A(6,7,8) | 119.9493 |
| A19 | A(7,8,9) | 119.6272 |
| A22 | A(8,9,10) | 120.4042 |
| A25 | A(5,10,9) | 120.7419 |
| A28 | A(1,18,19) | 120.4792 |
| A31 | A(18,19,20) | 128.0259 |
| A34 | A(19,20,21) | 123.4665 |
| A35 | A(19,20,25) | 118.4921 |
| A36 | A(21,20,25) | 118.0414 |
| A37 | A(20,21,22) | 120.8248 |
| A40 | A(21,22,23) | 120.3447 |
| A43 | A(22,23,24) | 119.6359 |
| A46 | A(23,24,25) | 119.9791 |
| A49 | A(20,25,24) | 121.1741 |

Table 7: C=C-C and C-C=O Bonding angles

Firstly, the oxygen-carbon-carbon region (2,1,3) had a slightly more obtuse value than the corresponding (17,1,2) region of the EE isomer. The bond angle for the (1,3,4) region is the main difference, with a more obtuse value of 127°, as compared to the 121° angle of the comparable (1,2,3) region of the EE conformer. This angle corresponds to the trans, or Z region of the conformer.

Finally, the skewed ZZ conformer was created and optimized at the B3LYP/6-311+G(d,p) level of theory in no solvent, after many attempts to create a sufficiently skewed conformer. The optimized bond lengths are as follows:

| Bond Name | Region | Bond Length (Å) |
|-----------|--------------|-----------------|
| R1 | R(1,2)C=O | 1.2269 |
| R2 | R(1,3) C-C | 1.4832 |
| R3 | R(1,18) C-C | 1.4832 |
| R4 | R(3,4) C=C | 1.3449 |
| R5 | R(3,17)C-H | 1.0854 |
| R6 | R(4,5) C-C | 1.4665 |
| R7 | R(4,16) C-H | 1.0864 |
| R8 | R(5,6) C-C | 1.4047 |
| R9 | R(5,10) C=C | 1.4061 |
| R10 | R(6,7) C=C | 1.392 |
| R12 | R(7,8) C-C | 1.3928 |
| R14 | R(8,9) C=C | 1.397 |
| R16 | R(9,10) C-C | 1.3887 |
| R19 | R(18,19) C=C | 1.3449 |
| R21 | R(19,20) C-C | 1.4665 |
| R23 | R(20,21) C=C | 1.4047 |
| R24 | R(20,25) C-C | 1.4061 |
| R25 | R(21,22) C-C | 1.392 |
| R27 | R(22,23) C=C | 1.3928 |
| R29 | R(23,24) C-C | 1.397 |
| R31 | R(24,25) C=C | 1.3887 |

Table 8: C-C, C=O, C=C, and the center C-H bond lengths for the ZZ Isomer

Here, the values once again remained consistent to the EE and ZE isomers. The angles were as follows:

| Angle | Location | Angle |
|-------|-----------------|----------|
| A1 | A(2,1,3) O=C-C | 118.9778 |
| A2 | A(2,1,18) O=C-C | 118.9779 |
| A3 | A(3,1,18) C=C-C | 122.0443 |
| A4 | A(1,3,4) | 125.4568 |
| A7 | A(3,4,5) | 127.1818 |
| A10 | A(4,5,6) | 118.6111 |
| A11 | A(4,5,10) | 123.2925 |
| A12 | A(6,5,10) | 118.0962 |
| A13 | A(5,6,7) | 121.1773 |
| A16 | A(6,7,8) | 119.9619 |
| A19 | A(7,8,9) | 119.6031 |
| A22 | A(8,9,10) | 120.41 |

| A40 | A(21,22,23) | 119.9619 |
| A43 | A(22,23,24) | 119.6031 |
| A46 | A(23,24,25) | 120.41 |

Table 9: C=C-C and C-C=O Bonding angles

Here, regions (2,1,3) and (2,1,18) involving the carbon oxygen bond had similar values to the corresponding (2,1,3) region from the ZE isomer. Compared to the ZE (1,3,4) trans-bonded side, the corresponding (1,3,4) and (1,18,19) carbon-carbon-carbon regions had slightly more acute bond angles.

The dihedral angles had to be studied to discover the true skewed nature of the ZZ conformer. The dihedral angles of carbons (1,2,4,5) from the central 2,4-pentadiene-3-one for each conformer was 359.983° for the EE, 179.992° for the ZE and 310.277° for the ZZ. While the EE and ZE conformers' dihedral angles had radian values of roughly 2π and π , the ZZ conformer had a $7\pi/4$ radian value for its dihedral angle. The ZZ isomer had a radian value of roughly

$31\pi/18$, far from an integer value multiplied by π . Whereas the sine values of the EE and ZE dihedral angles were roughly 0, the sine value of the ZZ dihedral angle was -0.766. Subtracting the dihedral angle from 360° obtained from placing the non skewed side of the ZZ conformer along the x axis, there is a 50° angle between the first and last carbons of the 2,4-pentadiene-3-ol chain.

IR Spectra

In order to confirm the existence of all three conformers and the findings of Venkateshwarlu and Subrahmanyam, their experiments had to be replicated. Solid DBZA was recrystallized from ethanol and dissolved in carbon tetrachloride, chloroform and dichloromethane. Two Perkin-Elmer Spectrum One FTIR Spectrometers were used to examine these mixtures.

Dichloromethane is the most polar solvent used in this experiment; so first, IR spectra had to be taken of just the solvent, to distinguish it from the eventual addition of DBZA. The spectrum changed drastically in the carbonyl region with an addition of DBZA using the same machine. This spectrum can be seen here, zoomed into the carbonyl region (1700 to 1475 cm^{-1}).

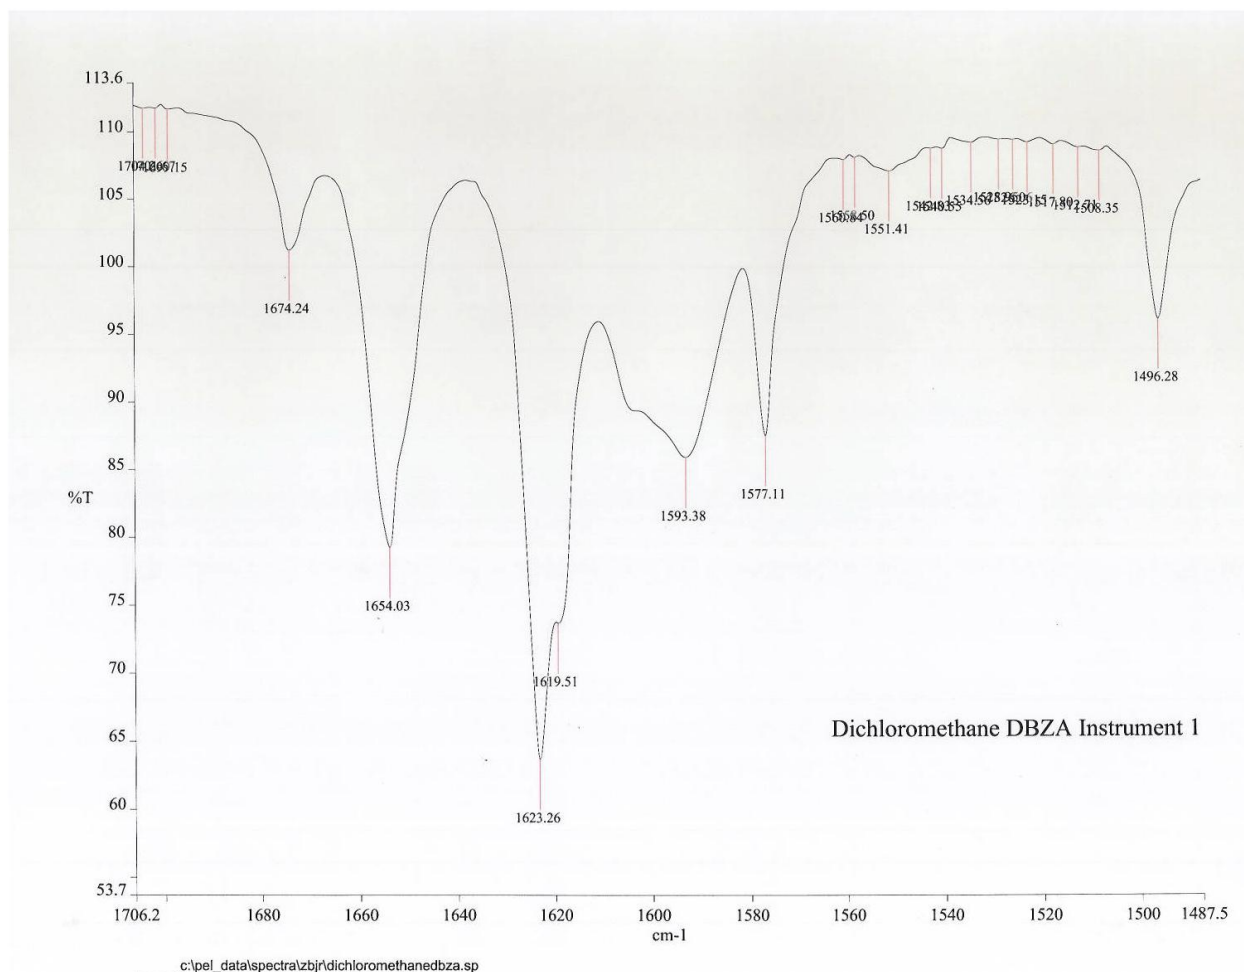

Figure 6: DBZA in Dichloromethane IR spectrum

Results show the main carbon-oxygen double bond peak at 1654 cm^{-1} , which corresponds to the ZE conformer (Venkateshwarlu and Subrahmanyam). The ZE peak, which dominates the ZZ shoulder peak, differs from the Venkateshwarlu and Subrahmanyam findings, where they hypothesized that their prominent ZZ peak was due to steric hindrance. The intensities as a whole were much lower than the Venkateshwarlu and Subrahmanyam experiment, yet the ratio of EE conformer was very comparable to the Venkateshwarlu and Subrahmanyam experiment. This low intensity points to a high ratio of solvent in the resultant DBZA in dichloromethane sample. A triplet carbon oxygen double bond value is visible, yet the

presence of more ZE than ZZ conformer distinguishes these results from Venkateshwarlu and Subrahmanyam's findings. A new DBZA in dichloromethane sample was prepared and scanned on the second machine.

Figure 7: DBZA in Dichloromethane IR spectrum, take 2

The second time the results from the first instrument repeated themselves, only the intensities decreased, as the percent transmittance rose five percent. The presence of the same triplet peaks and the same relative intensities indicates the results are reproducible. The first IR graph was compared with predicted intensities and frequencies from the optimized structures of the ZZ, EE, and ZE conformers in dichloromethane at the B3LYP/6-311+G(d,p) level of theory.

The computed frequency values had to be adjusted accounting for the scale factor of 0.9688, which was obtained by comparing the frequencies of B3LYP/6-311+G(d,p) calculations, to account for the difference between B3LYP/6-311+G(d,p) level of theoretical results and real world results. (Merrick et al, 2010). These adjusted frequencies are compared to the experimental percent transmission below.

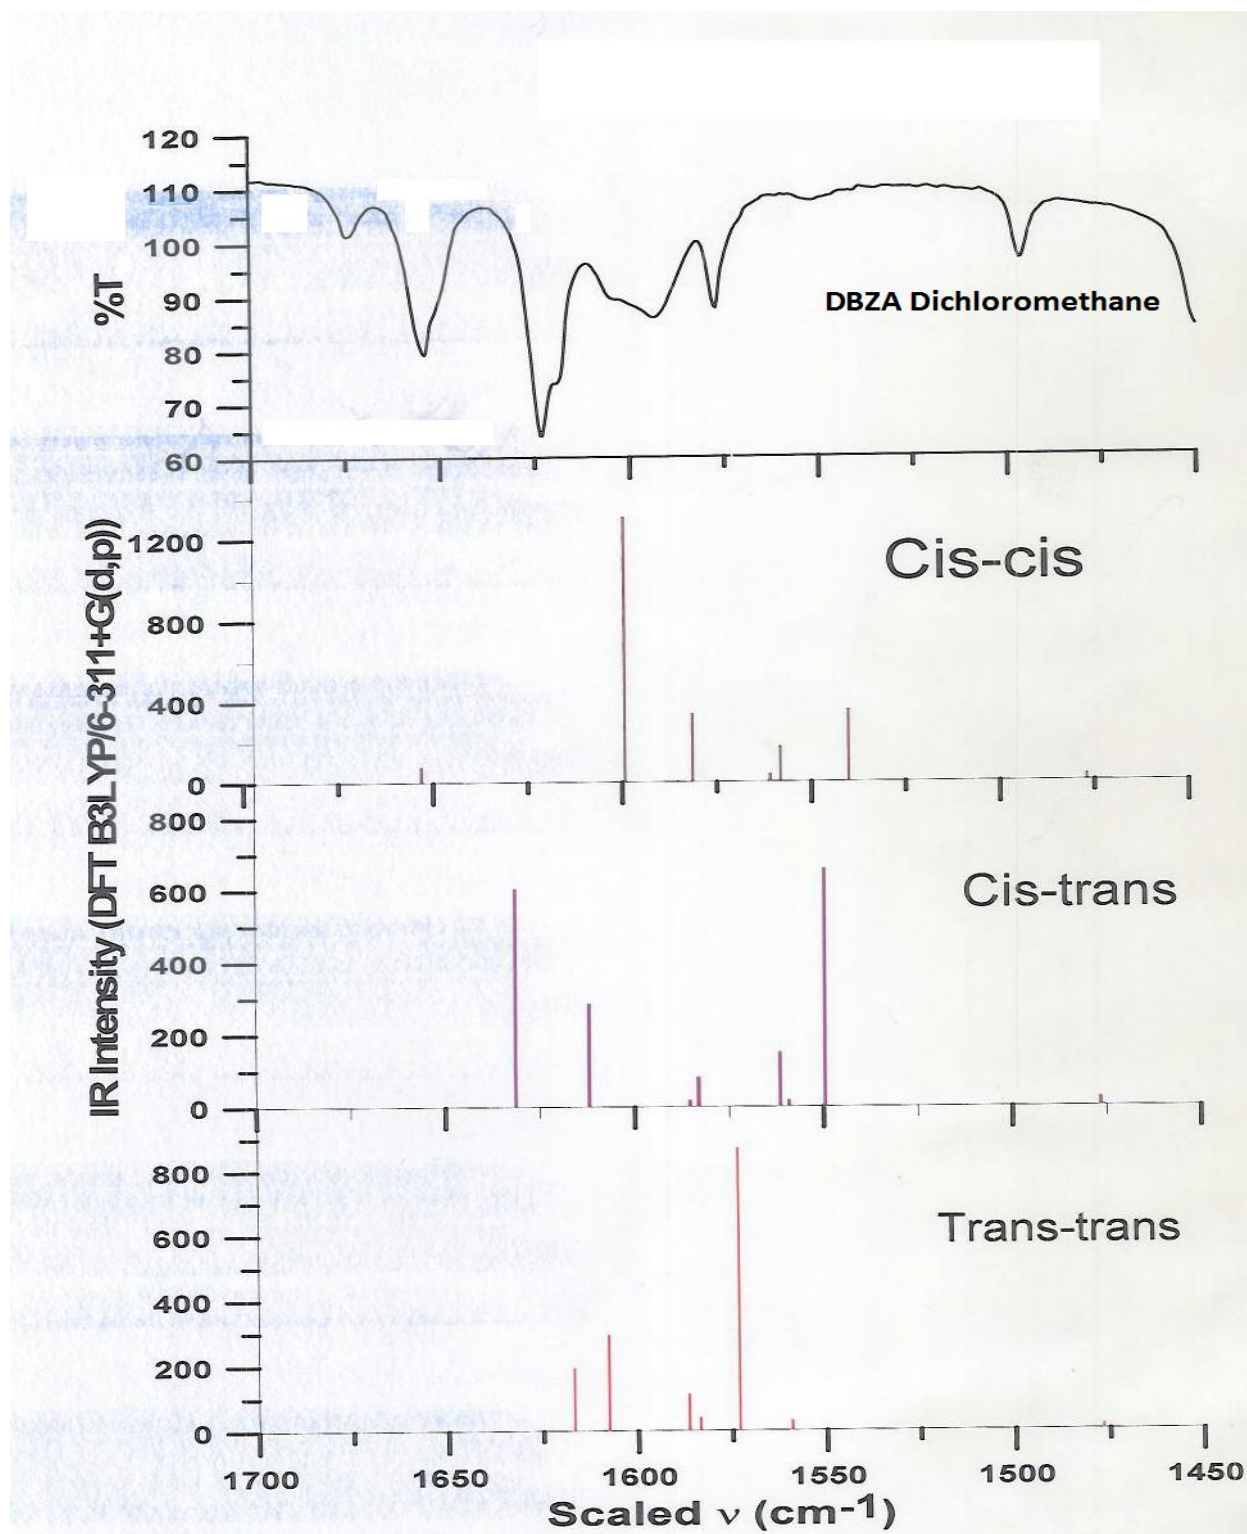

Figure 8: Second DBZA in Dichloromethane IR spectrum versus quantum molecular modeling predicted intensities and adjusted frequencies of DBZA in Dichloromethane

The strongly intense peaks from B3LYP/6-311+G(d,p) agree well to the intensities obtained experimentally. The ZE conformer's most intense peaks line up almost exactly with the most intense IR peak at about 1630 cm⁻¹. This correlates strongly with experimental data, showing the ZE conformer as being dominant in both mixtures of DBZA in dichloromethane. These findings are compared in Table 10.

| EE adjusted frequency | EE Intensity | ZE adjusted frequency | ZE Intensity | ZZ adjusted frequency | ZZ intensity | Experimental frequency | Experimental intensity |

Table 10: DBZA computer predicted versus experimental intensities

The values computed by quantum molecular modeling and adjusted to scale may not be a perfect fit, yet they do show a ratio of ZE>ZZ>EE in dichloromethane based on closeness of the highest intensity peaks to the lowest percent transmittance regions of the IR spectrum.

The next most polar solvent was chloroform (CHCl_3). The actual IR spectrums of DBZA in chloroform were taken with the same procedure used for DBZA in dichloromethane.

Figure 9: DBZA in chloroform IR spectrum

Here, the largest carbon-oxygen double bond peak lies at 1652 cm^{-1} , which is between the ZE and the ZZ values, and is closer to the ZE. The triplet peak just below 1650 cm^{-1} exists in roughly the same ratios to the ZE and EE peak intensities as in the first DBZA in dichloromethane spectra. The ZZ shoulder peak's relative intensity is much lower than in Venkateshwarlu and Subrahmanyam's findings.

This experiment was done again on a second machine with a new mixture of DBZA in chloroform.

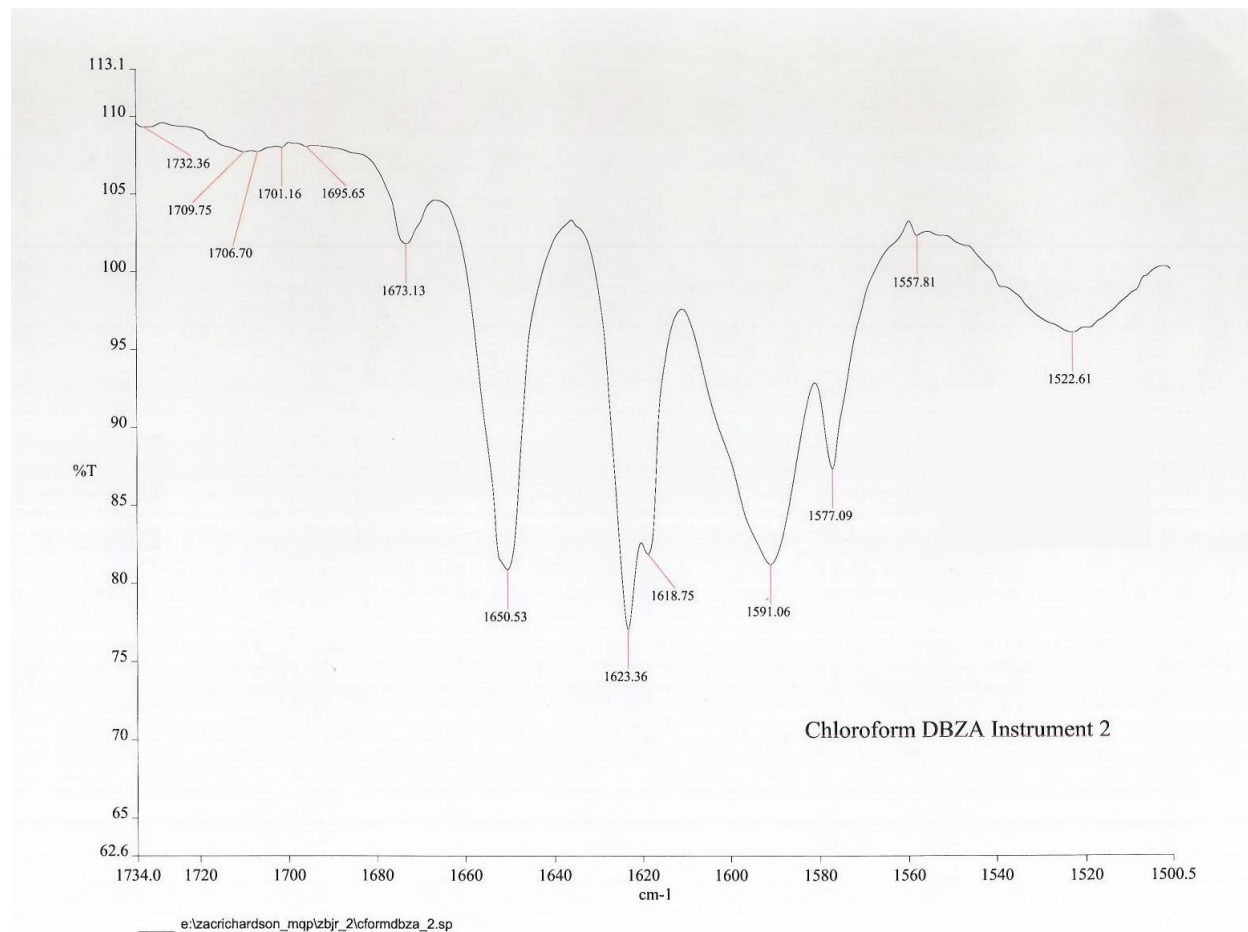

Figure 10: DBZA in chloroform IR spectrum take 2

Here, with the most intense carbon-oxygen double bond region peak measured at 1650.5 cm⁻¹, the spectrum shows that peak has a distinct shoulder with a slightly higher frequency. Even the carbon-carbon double bonding region shows a distinct shoulder peak. Only the intensity and frequency of the EE peak remains the same as in the first experiment. Here, the frequency of the 1650.5 cm⁻¹ peak is slightly higher than its counterpart whose frequency matches the ZE region of Venkateshwarlu and Subrahmanyam's graph. Compared to

the corresponding Venkateshwarlu and Subrahmanyam experiment, the shape of the 1645-1655 cm^{-1} peak is exactly the same, if not for the fact that Venkateshwarlu and Subrahmanyam found the ZE conformer to be slightly more frequent than the ZZ, based on the intensities of their IR spectrum.

The second experiment correlates more strongly to the researched values (Venkateshwarlu and Subrahmanyam). Thus, the experimental IR spectrum from the second machine was compared to the intensities and adjusted frequencies obtained through quantum molecular modeling of all three conformers' for optimized geometries and vibrational frequencies in chloroform.

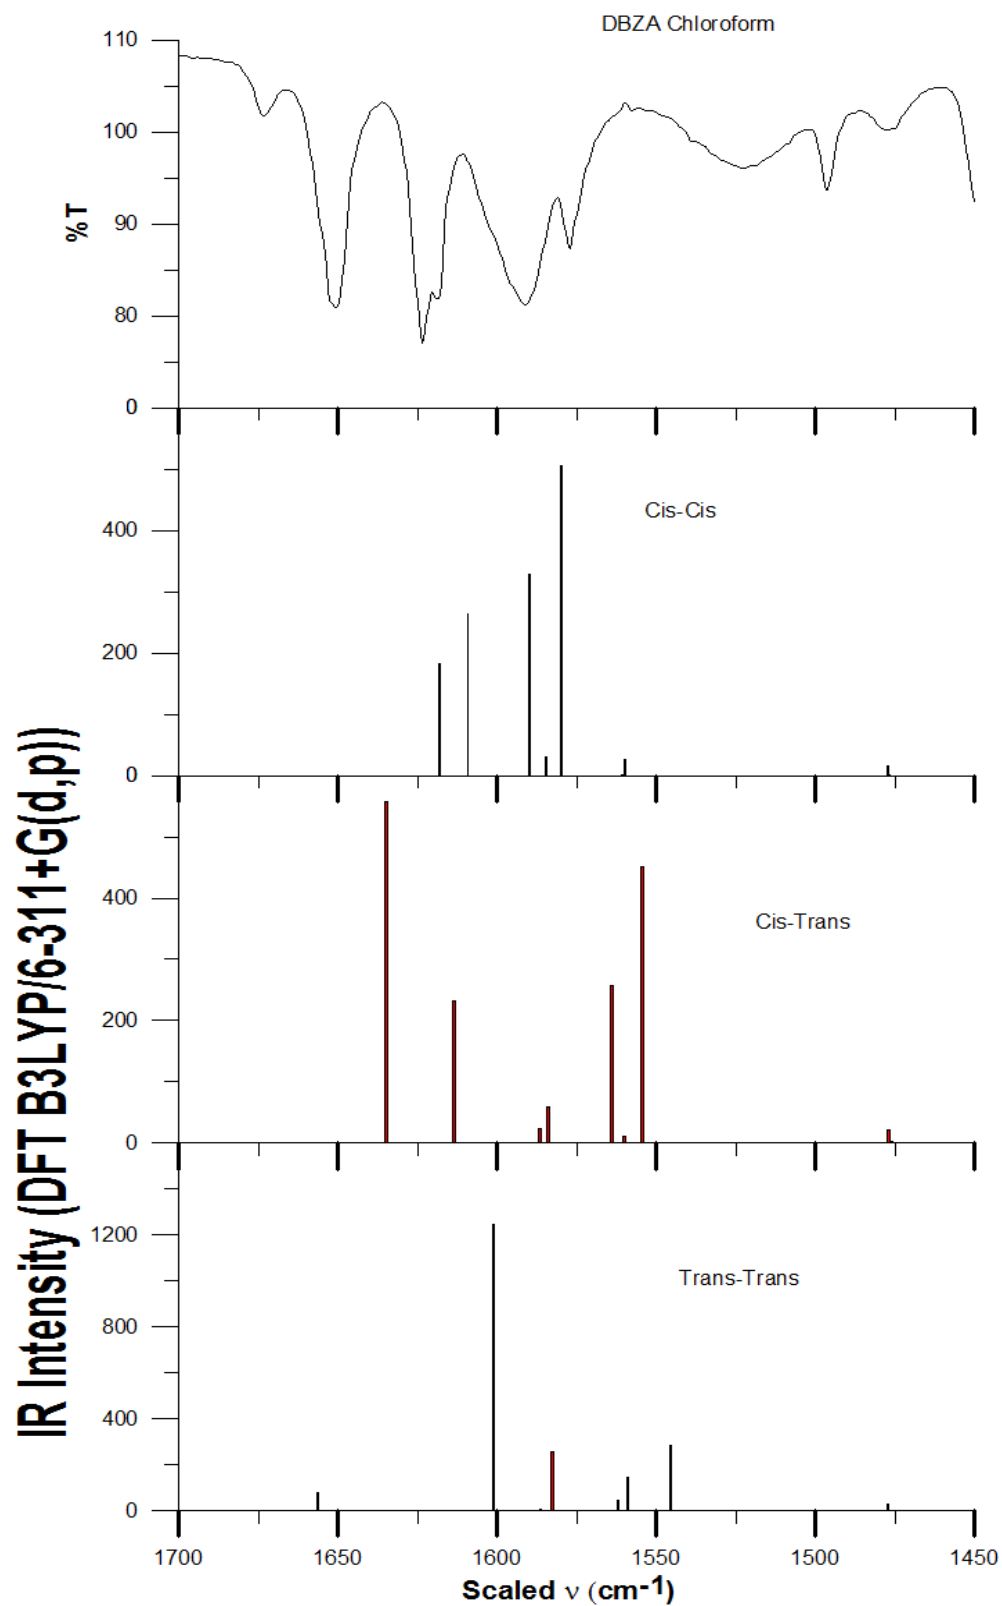

Figure 11: Second DBZA in Chloroform IR spectrum versus quantum molecular modeling predicted intensities and adjusted frequencies of DBZA in Chloroform

All three conformers have highly intense peaks which correlate somewhat to the IR spectrum, with the ZZ isomer making a direct connection at 1601 cm^{-1} . The ZE isomer has high intensity peaks very close to high intensity regions of the IR spectrum. This correlates to results showing ZZ>ZE>EE.

Table 11 directly compares the experimental and computational values. This is to show the values as plain numbers rather than merely interpret them from a graph.

| EE adjusted frequency | EE Intensity | ZE adjusted frequency | ZE Intensity | ZZ adjusted frequency | ZZ intensity | Experimental frequency | Experimental intensity |
|-----------------------|--------------|-----------------------|--------------|-----------------------|--------------|------------------------|------------------------|
| 1476.658 | 0.7124 | 1476.108 | 3.1595 | 1476.843 | 0.5509 | 1476 | 56.1481 |

Table 11: DBZA computer predicted versus experimental intensities

These values, though not perfect, show that the ZE and ZZ isomers are much more present than the EE. Also, the ZZ peaks still fit the experimental results more closely than the ZE peaks.

Carbon tetrachloride is the last and least polar solvent studied. The experiment was done again in carbon tetrachloride.

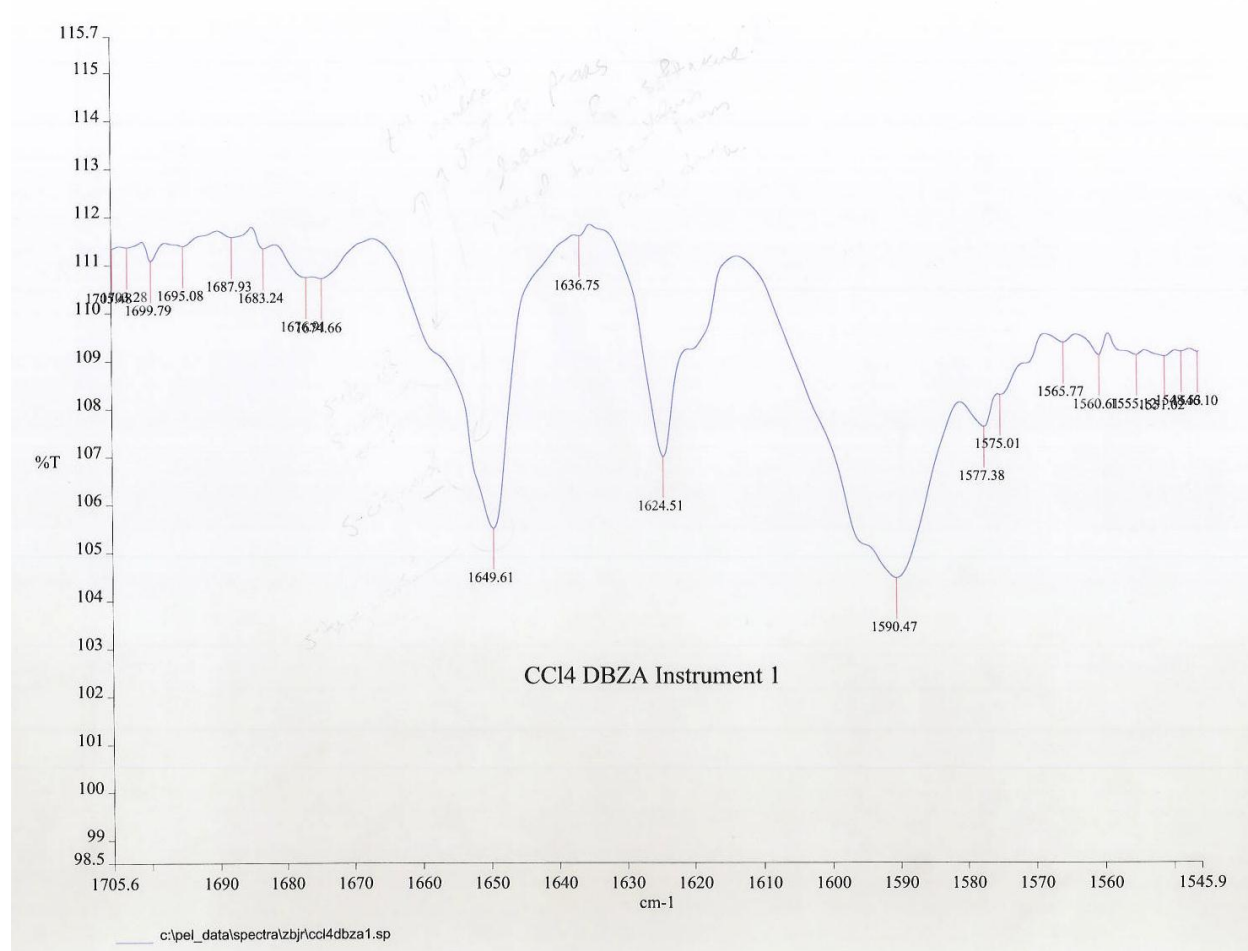

Figure 12: DBZA in CCl₄ Spectra machine 1

The main carbon-oxygen double bond region peak is at 1649.61 cm⁻¹. This value continues a trend of differing from Venkateshwarlu and Subrahmanyam's results, where the

main peak stood at 1654 cm^{-1} , which was in the ZE region. This experimental peak corresponds to the ZZ conformer region, which Venkateshwarlu and Subrahmanyam believed was sterically hindered in non polar solvent. The intensities of these peaks are very low compared to the dichloromethane and chloroform spectra, with the exception of the EE peak. This correlates to the Venkateshwarlu and Subrahmanyam findings, where the carbon tetrachloride intensities were lower in general, and the relative intensity of the EE peak is higher than in the first two solvents.

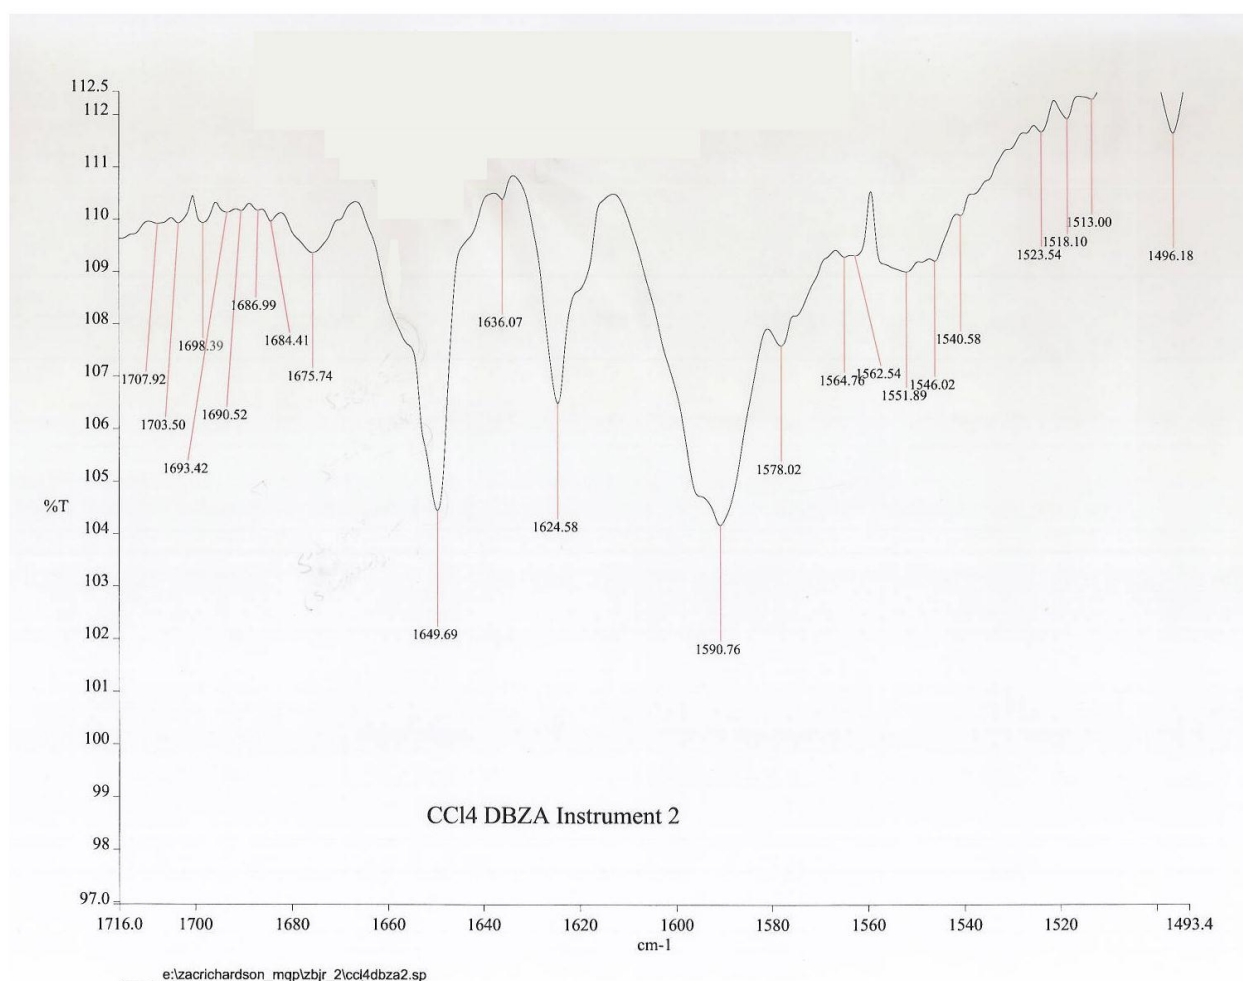

Figure 13: DBZA in CCl₄ Spectra machine 2

Once again, results are exactly the same, proving the experiment is reproducible. The first experiment had higher intensities, so it was compared to theoretical values.

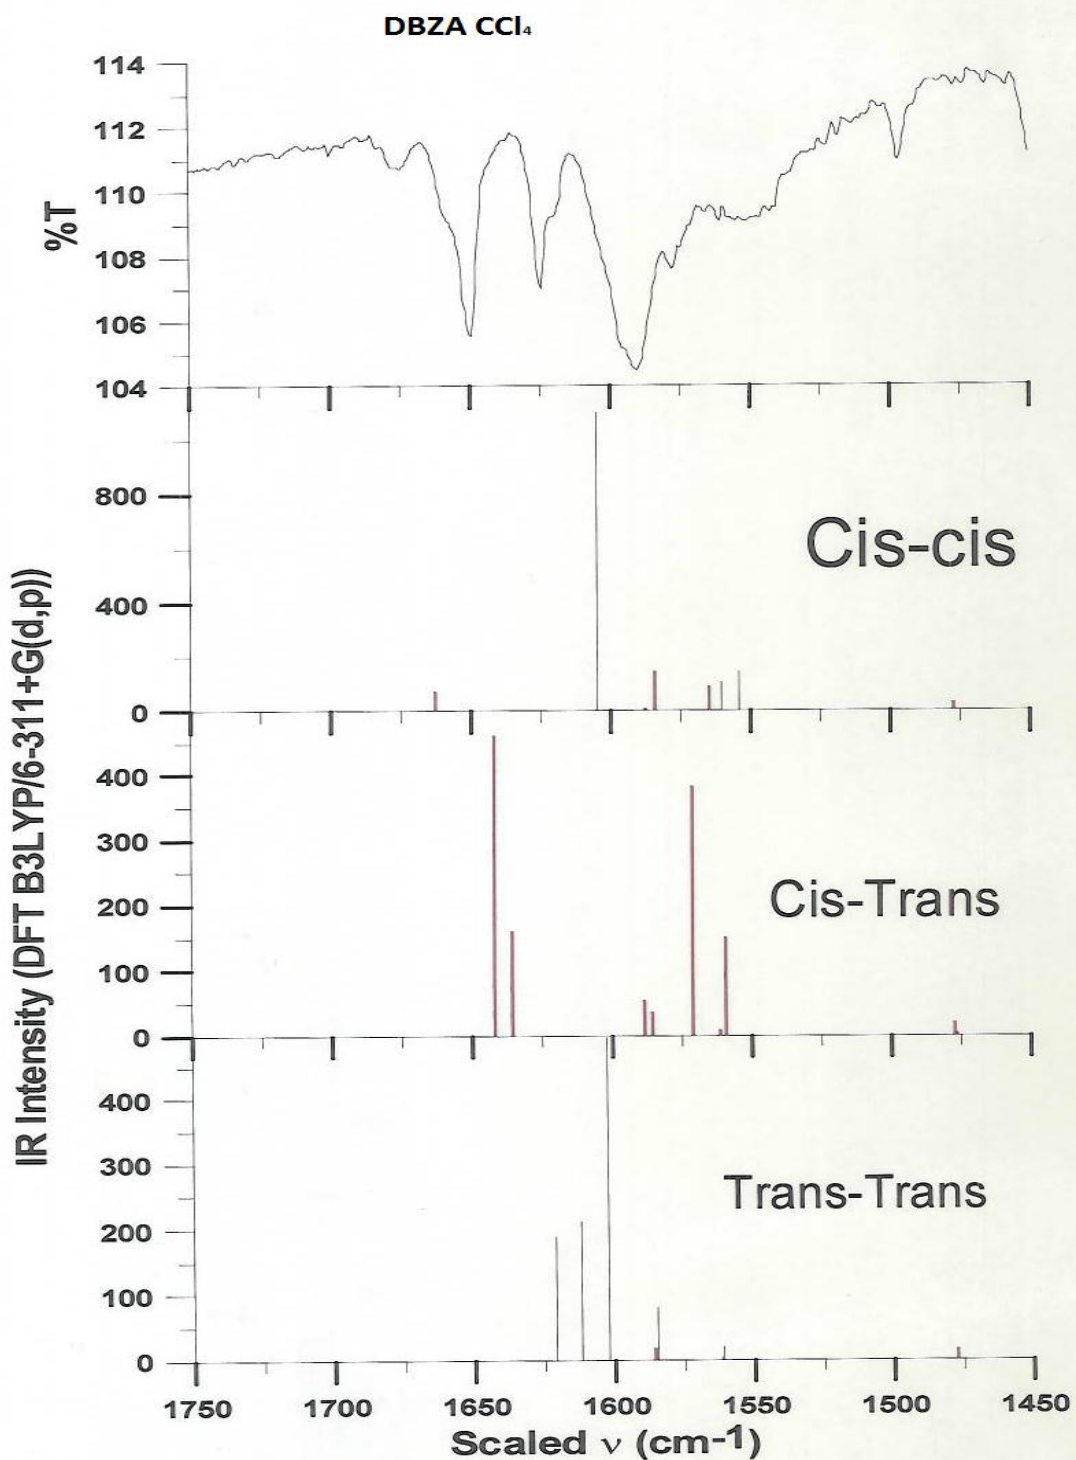

Figure 14: Second DBZA in carbon tetrachloride IR spectrum versus quantum molecular modeling predicted intensities and adjusted frequencies of DBZA in carbon tetrachloride

These values can be compared by this chart:

| EE adjusted frequency | EE Intensity | ZE adjusted frequency | ZE Intensity | ZZ adjusted frequency | ZZ intensity | Experimental frequency | Experimental intensity |
|-----------------------|--------------|-----------------------|--------------|-----------------------|--------------|------------------------|------------------------|
| 1477.224 | 0.6203 | 1476.701 | 2.9888 | 1477.179 | 1.3024 | 1477 | 113.193 |

| | | | | | | 1604.5 | 108.73 |
| | | | | | | 1611.5 | 110.976 |
| | | | | | | 1620.5 | 109.236 |
| | | | | | | 1635.5 | 111.815 |
| | | | | | | 1642 | 111.028 |
| | | | | | | 1663 | 110.837 |

Table 12: DBZA computer predicted versus experimental intensities

Values in all six experiments showed that the EE conformer is sterically hindered by chlorine rich solvents. The exact proportions of ZZ and ZE conformers and which one dominates depend on the mass of the solvent, rather than solely on its polarity.

UV-Vis Absorbance Studies of DBZA

The UV-Vis absorbance characteristics of DBZA were studied next. Using time-dependent density functional theory (TD-DFT), the absorbance characteristics and energies of each molecular orbital and energy state were calculated. The highest occupied molecular

orbital (HOMO), is shown for the highest bonding and non-bonding orbitals below for the EE isomer, as well as the lowest unoccupied molecular orbital (LUMO). These orbital shapes are shown below for the EE isomer.

HOMO (π)

MO 62

LUMO (π^*)

MO 63

Figure 17: ZZ conformer Molecular orbitals

For all three conformers, the LUMO is molecular orbital number 63 and the HOMO for bonding and nonbonding orbitals are molecular orbitals 62 and 60, respectively. In all three cases, the LUMO is a π^* antibonding orbital, molecular orbital 62 is π bonding, and molecular orbital 60 is a nonbonding orbital localized on the carbonyl oxygen atom. With these same calculations, done at the DFT B3LYP/6-311+G(d,p) level of theory, the actual molecular orbital data could be found. This entailed the transition energies, oscillator strengths, and wavelengths for each state, as well as the configuration interaction coefficients for each molecular orbital transition at that level. The computed values at this level of theory are presented in Table 13.

| Isomer | State | Transition energy (eV) | Transition frequency (cm ⁻¹) | Transition λ (nm) | Oscillator strength | MO | CI Coefficient |

Table 14: Molecular energies of all three conformers

The DBZA in n-hexane absorption spectra experiment had to be done twice. First, absorbance was run in order to observe $\pi^* \leftarrow n$ absorbance at around 360 nm (Hoshi et al). Next, DBZA was diluted thirty-fold from stock concentrated solution in experiment one in order to recognizably view the $S_2(\pi, \pi^*)$ absorbance band.

Figure 18: Experimental UV-visible spectra of DBZA and 30 times diluted DBZA in n-Hexane

These results match the Hoshi et al results perfectly in terms of peak shapes and frequencies except the peak of the third transition state is just slightly skewed right. The intensity values are twice as high as those obtained by Hoshi et al in both experiments, which

once again indicates a difference in concentration of solute versus solvent. Comparing these results to those obtained theoretically gives a different picture.

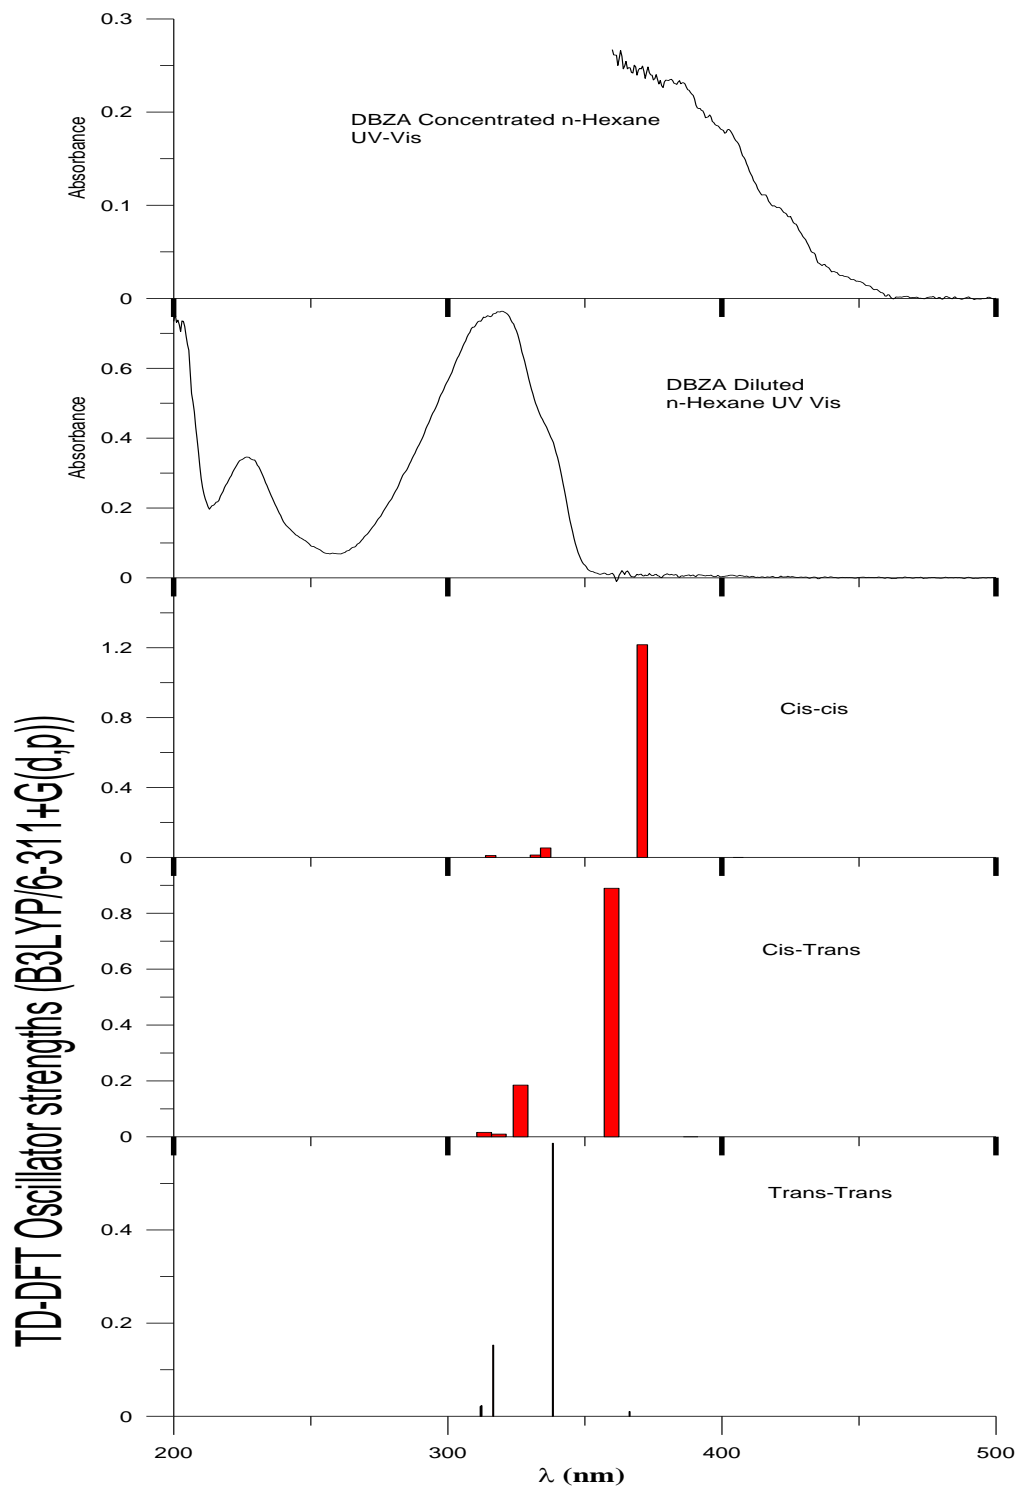

Figure 19: Grapher comparison of wavelength versus absorbance for experimental and computed DBZA in n-Hexane UV-visible spectra

The graph shows the presence of all three conformers. The EE conformer has its strongest peak in a lower absorbance section of the spectra than the ZZ and ZE conformers do, but not by very much. This shows that even in non halogenated solvents, the EE conformer is at least somewhat sterically hindered. To compare these values further, they are presented in the table below.

| EE λ (nm) | Oscillator strength | ZE λ (nm) | Oscillator strength | ZZ λ (nm) | Oscillator strength | Experimental λ (Concentrated) (nm) | Experimental Absorbance (Concentrated) |
|-------------------|---------------------|-------------------|---------------------|-------------------|---------------------|--|--|

Table 16: Molecular energies of all three conformers

The actual experiment involved dilute DBZA in chloroform. Here is the spectrum of results.

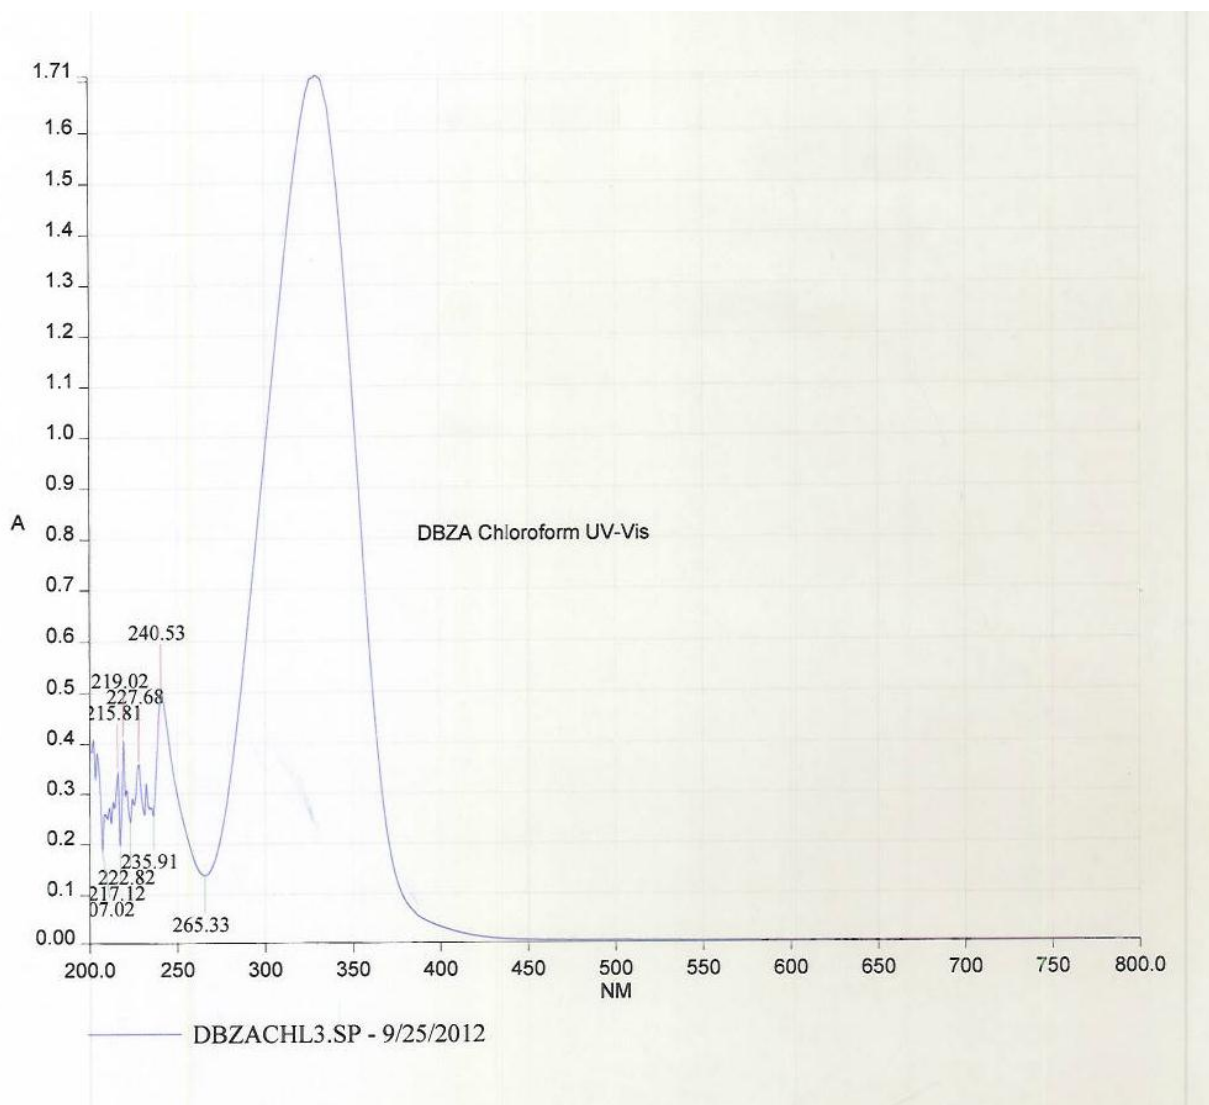

Figure 20: UV-Vis spectra of DBZA in Chloroform

The results show a much higher absorbance than in n-Hexane, so the n to π^* transition can be observed along with all the other transition states in one experiment. Molecular absorbance values from this experiment had to be compared to theoretical absorbance values and wavelengths.

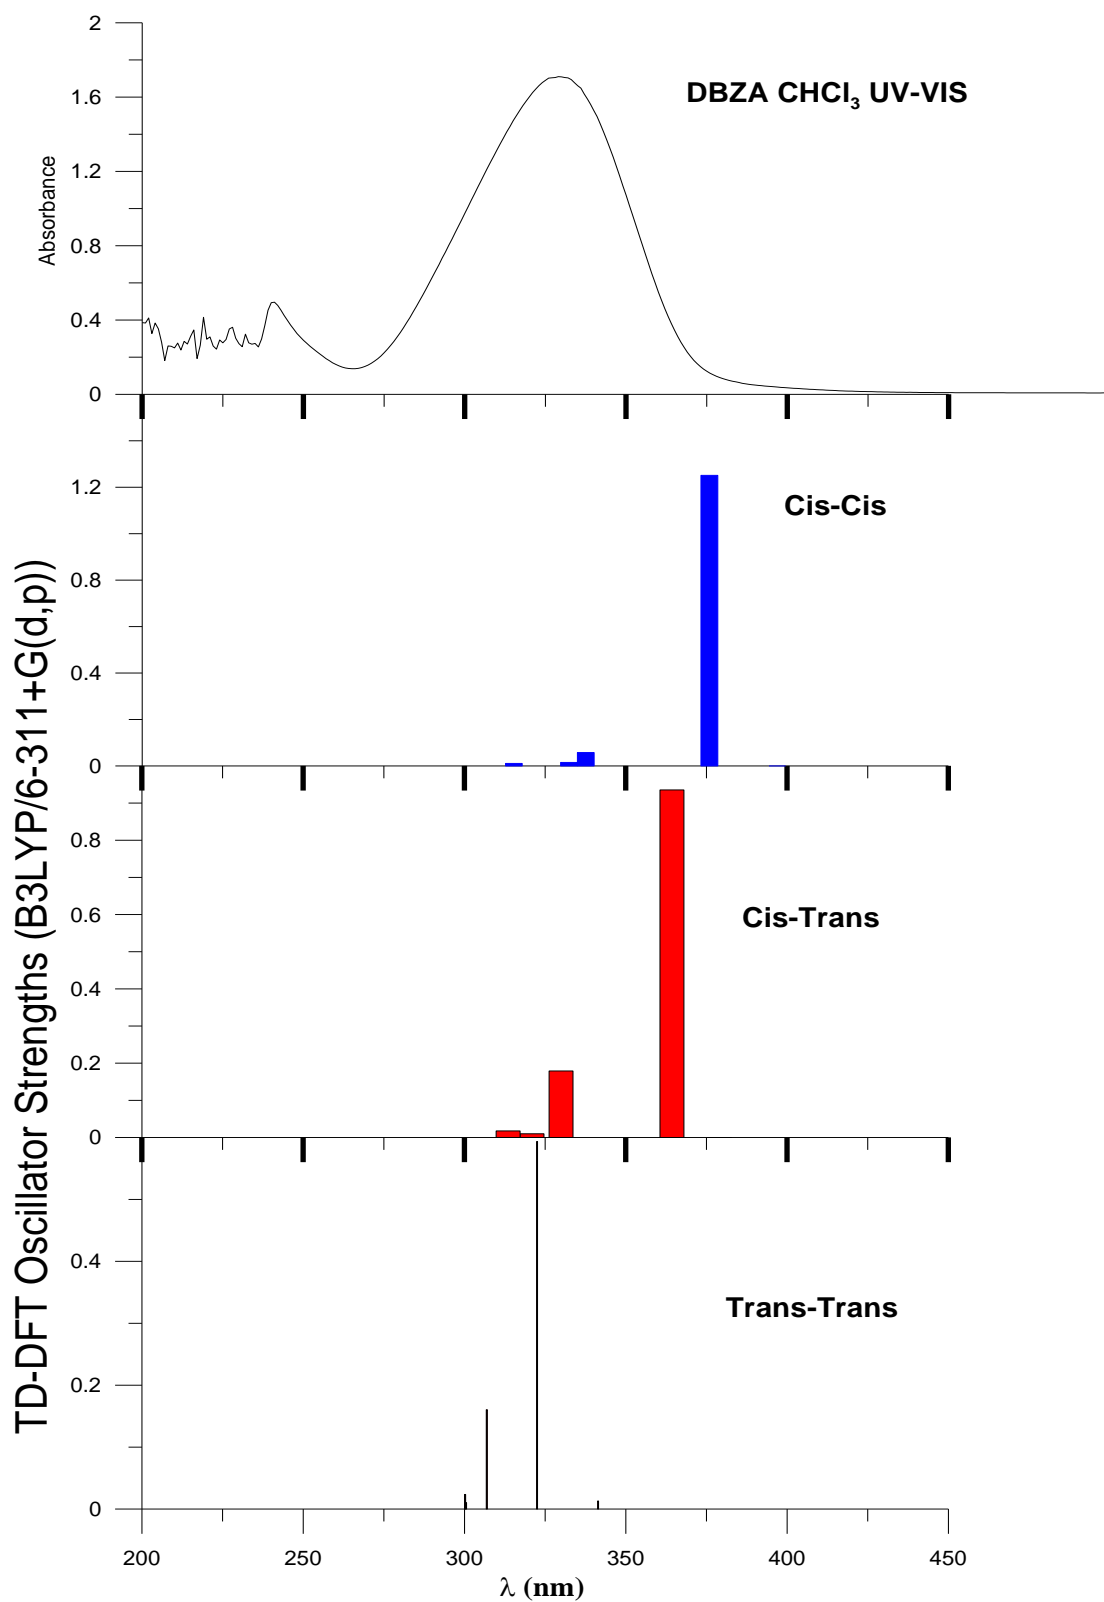

Figure 21: Grapher comparison of wavelength versus absorbance for experimental and computed DBZA in CHCl₃ UV-visible spectra

The ZZ conformer stands head and shoulders above the ZE and the EE conformers in terms of prevalence from the given experimental spectra. These values are compared in this table.

| EE λ (nm) | Oscillator strength | ZE λ (nm) | Oscillator strength | ZZ λ (nm) | Oscillator strength | Experimental λ (nm) | Experimental Absorbance |
|-------------------|---------------------|-------------------|---------------------|-------------------|---------------------|-----------------------------|-------------------------|
| 397 | 0 | 379 | 0 | 341 | 0.0129 | 300 | 0.97411 |
| 376 | 1.2513 | 364 | 0.9354 | 322 | 0.5934 | 301 | 1.0085 |
| 338 | 0.0578 | 330 | 0.1789 | 307 | 0.1603 | 307 | 1.21712 |
| 332 | 0.0148 | 321 | 0.0101 | 300 | 0.0104 | 314 | 1.44145 |
| 315 | 0.0108 | 314 | 0.0177 | 300 | 0.0235 | 315 | 1.47318 |

| | | | | | | 330 | 1.70878 |
| | | | | | | 332 | 1.70335 |
| | | | | | | 338 | 1.58998 |
| | | | | | | 341 | 1.49546 |
| | | | | | | 364 | 0.38175 |
| | | | | | | 376 | 0.11386 |
| | | | | | | 379 | 0.09059 |
| | | | | | | 397 | 0.03903 |

Table 17: Comparison of quantum molecular modeling versus experimental absorbance of DBZA in chloroform

The computed values line up nicely with the experimental ones. The experiment was a success.

Conclusions

DBZA does indeed form three conformers under various conditions and in certain solvents. The proportions of these isomers vary when DBZA is dissolved in carbon tetrachloride, chloroform, and dichloromethane. The EE conformer may be the major form in the solid state of DBZA in air, but in all solvents tested, it is sterically hindered to the point of being the least prevalent of the three. Whether the ZE or skewed ZZ conformer comes to dominate depends on the size of solvent and concentration of the solute, and not just on solvent polarity.
